Overview

Patients with esophageal cancer have several treatment options at their disposal. One new treatment in the toolbox to fight cancer is proton therapy. Physicians at the Maryland Proton Treatment Center (MPTC) use the most advanced form of proton therapy, called pencil-beam scanning (PBS), or intensity modulated proton therapy (IMPT) to target tumors with unmatched precision, while minimizing damage to surrounding healthy tissue.

Delivery of radiation dose for esophageal cancers is limited by potential damage to the nearby heart and lungs. Radiation dose received by the heart and lungs is known to potentially cause both short-term and long-term complications, so minimizing dose to these important organs is critical. Given these risks, proton therapy can be an attractive option for patients with esophageal cancer because it is a noninvasive option that can substantially reduce the radiation dose to critical structures such as the lungs and heart. A 2015 study comparing proton therapy with intensity modulated radiation therapy (IMRT) found that proton therapy “can further reduce mean lung/heart dose in esophageal cancer.”

Studies have shown that proton therapy for esophageal cancer is well tolerated. In addition to a reduced risk of normal tissue injury, proton therapy may also allow for higher radiation dose to be safely delivered to tumor in the esophagus, which may provide a higher probability that the tumor will be controlled. Protons allow for re-irradiation. Proton therapy may be used in esophageal cancer patients who receive chemoradiation prior to surgery, chemoradiation without surgery, or in patients who have had prior radiation for esophageal cancer.

Proton therapy is likely to benefit:

- **Patients with operable or non-operable esophageal cancer:** The precision of proton therapy allows for a greater oncologic benefit to the patient while minimizing radiation dose to critical thoracic structures.
- **Patients who have had prior chest radiation therapy:** When any part of the body is radiated a second time, the risk of short- and long-term side effects increases. For this reason, patients who have previously received radiation to the chest from prior cancers (breast, lung, lymphoma, etc.) are often good candidates for proton therapy’s precision targeting.
- **Patients with disease recurrence:** Proton therapy can aim a higher dose of radiation at the site of the recurrence, potentially leading to improved outcomes. Proton therapy’s precision can reduce the radiation dose that surrounding normal tissues, including the heart and lungs, receive.

Proton Therapy Versus Photon Therapy

Because of the physics of proton particles, proton radiation goes to the site of the tumor and stops. The image above shows the areas surrounding the esophageal tumor exposed to radiation (dose delivered to tumor and surrounding tissue shown in color) during treatment. Proton therapy (left) delivers significantly less radiation to the surrounding areas than the photon treatment (right).

MPTC-Specific Clinical Trial Offerings
MPTC is dedicated to advancing scientific knowledge about the role of proton therapy in the treatment of esophageal cancer. All patients treated at MPTC have access to a wide range of clinical trials available through the Maryland Proton Alliance.

Plans are also underway at MPTC to open in-house clinical trials in addition to multi-institutional trials. For example, physicians at MPTC are developing a dose escalation trial for inoperable esophageal cancer.

Current clinical trials at MPTC include:
- NCT01255748: Evaluation Tracking Project: A Prospective Chart Review of Patients Treated with Radiation Therapy
- NCT01512589: Phase III Randomized trial of Proton Beam Versus Intensity-Modulated Radiation Therapy for the Treatment of Esophageal cancer (coming soon)

For information on our currently available clinical trials, please call our research department at 410-369-5335.

About the Maryland Proton Treatment Center
The Maryland Proton Treatment Center is affiliated with the University of Maryland Marlene and Stewart Greenebaum Comprehensive Cancer Center, an NCI-designated comprehensive cancer center. MPTC is focused on clinical excellence, affordability, accessibility, as well as comfort and convenience for your patients. In addition, our team has initiated the Maryland Proton Alliance to bring the latest research and clinical trials to patients and physicians. We have taken a leadership role in the industry by offering proton therapy at the same cost as IMRT.

Outcomes
Your patients may be hesitant to explore new treatment options for esophageal cancer and may pose questions related to side effects and outcomes. Proton therapy is an effective, noninvasive, low-risk treatment option that can improve the quality of life for cancer patients and survivors. Studies are ongoing, and early results confirm this treatment’s power and precision.

Proton therapy’s unique properties can improve outcomes for patients with esophageal cancer. Our 2016 study found that “a growing body of evidence indicates that further risk reductions are achieved with proton beam therapy” as compared to photon therapy. A 2012 study of outcomes of proton therapy and concurrent chemotherapy for esophageal cancer concluded that “the pathologic response and clinical outcomes are encouraging.”

Published Research
The Maryland Proton Treatment Center is led by nationally recognized radiation oncologists from the University of Maryland School of Medicine who are involved in cutting-edge research and clinical trials. In 2016, Jen Yu, PhD, Shahed Badiyan, MD, and Mark V. Mishra, MD published a multi-institutional review of dosimetric and clinical literature on treating esophageal cancer with proton therapy.

Contact Information
To refer a patient or to discuss treatment options with one of our physicians, please call 410-369-5200 or email us at info@mdproton.com.
